Tables S1–S2
References

Text S1.

The following equations were used to calculate the alloy properties plotted in Figure 6 of the main text. All equations are functions of differential stress τ . Modified from Gleason and Mao (2013), Reaman et al. (2011), and references therein. Parameter values are listed in Table S1.

$$\text{Dislocation velocity:} \quad v = \left(\frac{v_D a' b L}{w^2} \right) \exp\left(\frac{-\Delta H_0}{kT}\right) \sinh\left(\Delta H_0 - \frac{\Delta H}{kT}\right) \quad (\text{S1})$$

$$\text{Activation enthalpy:} \quad \Delta H = \Delta H_0 \left[1 - \left(\frac{\tau_p}{\tau} \right)^{3/4} \right]^{4/3} \quad (\text{S2})$$

$$\text{Strain rate:} \quad \dot{\epsilon} = b v \left(\frac{\tau}{G_0 b} \right)^2 \quad (\text{S3})$$

$$\text{Critical grain size:} \quad d = \sqrt{\frac{A_{Dif} V k}{A_{Dis} b R} \ln\left(\frac{\alpha G}{2S\tau}\right) \left(\frac{G}{\tau}\right)^n} \quad (\text{S4})$$

Figure S1.

Observed change of Q upon laser heating of Fe-5Si. The 300 K point (upper left) was calculated from the Fe-5Si fit (main text Figure 3). High temperature data are from consecutive diffraction images collected at approximately the same pressure (43–46 GPa; see main text Figure 2). Dashed lines are 95% confidence intervals.

Figure S2.

Comparison between our experimentally-determined ratio of hcp unit cell parameters (i.e., the ratio of c-axis length and a-axis length) and the ratio calculated using the parametrization of Fischer and Campbell (2015). ‘Mismatch’ here is defined

as $\left(\frac{\text{measured } c/a - \text{calculated } c/a}{\text{calculated } c/a}\right) \times 100$. Despite the nonhydrostatic conditions of our radial

diffraction experiments, the measured and calculated unit cell ratios agree quite well at 300 K.

composition	phases	T (K)	P (GPa)	hcp c (Å)	hcp a (Å)	Q

Table S1.

Data from our radial diffraction experiments. All data were collected at Advanced Light Source beamline 12.2.2 (Kunz et al., 2005). Asterisks indicate diffraction images taken during sample decompression. Compositions are in weight percent. Q is the average of all observed sample peaks (see main text for details). Numbers in parentheses are uncertainties on the last digit(s). Pressures were calculated from the equation of state of Pt (Fei et al., 2007) at 300 K or MgO (Speziale et al., 2001) at high temperatures. Temperature measurement is described in Kunz et al. (2018).

Parameter		Value	Source
Debye frequency	V_D	13 THz	Gleason and Mao (2013)
Peierls barrier width	a'	0.2 nm	Gleason and Mao (2013)
Burgers vector	b	0.5 nm	Gleason and Mao (2013)
Kink pair width	w	20 nm	Gleason and Mao (2013)
Dislocation length	L	500 nm	Gleason and Mao (2013)
Standard activation enthalpy	ΔH_0	6 eV	Gleason and Mao (2013)
Peierls stress	τ_p	varies	This study
Aggregate shear modulus	G	varies	This study; Gleason and Mao (2013); Regan et al. (2018)
Ambient aggregate shear modulus	G_0	varies	This study; Gleason and Mao (2013); Regan et al. (2018)
Geometrical constant of diffusion	A_{Dif}	30	Reaman et al. (2011)
Geometrical constant of dislocation	A_{Dis}	1.8	Reaman et al. (2011)
Schmid factor constant	$\alpha/2S$	0.6	Reaman et al. (2011)
Power-law constant	n	2	Reaman et al. (2011)
Specific volume	V	varies	Dewaele et al. (2006); Fischer et al. (2014)

Table S2.

Parameters used in Equations S1–S4. We retain the values used in previous studies, except for Peierls stress, which we set equal to our recalculated strength (main text Figure 5), and specific volume, which we recalculated for the alloy compositions used (assuming that the effect of Ni is negligible).
